Introduction

Pre-Lab Exercises

In this chapter, we have provided our solutions to some theoretical questions that were needed to be solved before conducting the experiment. All the equations and standard values of parameters used to calculate the numerical results for these exercises are taken from [1], unless mentioned otherwise.

0.1 Calculation of partial decay widths for $Z^0 \rightarrow f\bar{f}$

In this exercise, we are required to calculate the partial decay widths of $Z^0 \rightarrow f\bar{f}$; where $f\bar{f}$ represent the following fermion-antifermion pairs : (i) e^+e^- (ii) $\mu^+\mu^-$ (iii) $\tau^+\tau^-$ (iv) $q\bar{q}$, where q represents all the flavours of quarks (except for t quark, because it is too heavy ($M_t \approx 172.76$ GeV [2]) to be produced from Z^0 decays). The partial decay widths have been calculated with the following formula:

$$\Gamma_f = \frac{N_c^f \sqrt{2}}{12\pi} G_F M_Z^3 \left((g_V^f)^2 + (g_A^f)^2 \right) \quad (1)$$

where:

N_c^f : colour factor, (1 for leptons, 3 for quarks)

$G_F = 1.16637 \times 10^{-5} \text{GeV}^{-2}$, Fermi's constant

$M_Z = 91.182$ GeV, mass of Z^0 boson

$g_V^f = I_3^f - 2Q_f \sin^2 \theta_W$, vector coupling strength of Z^0 to fermions

$g_A^f = I_3^f$, axial-vector coupling strength of Z^0 to fermions

Q_f : electric charge of fermion f

I_3 : third component of weak isospin

$\sin^2 \theta_W = 0.2312$, θ_W is the Weinberg (weak-mixing) angle

Fermion	Q_f	I_3^f	g_V^f	g_A^f	N_c^f	$\Gamma_f^{(\text{calc})} / \text{MeV}$	$\Gamma_f^{(\text{ref})} / \text{MeV}$
e^-, μ^-, τ^-	-1	-0.5	-0.0376	-0.5	1	83.89	83.8
u, c	2/3	0.5	0.1917	0.5	3	285.34	299
d, b, s	-1/3	-0.5	-0.3459	-0.5	3	367.84	378
ν_e, ν_μ, ν_τ	0	0.5	0.5	0.5	1	165.85	167.6

Table 1: Parameters $Q_f, I_3^f, g_V^f, g_A^f, N_c^f$ for various fermion pairs and their partial decay widths

The calculated partial decay widths for the required fermion pairs have been listed under $\Gamma_f^{(calc)}$ in Table 1. Further, the reference [1] values of partial decay widths for the same fermion pairs are listed under $\Gamma_f^{(ref)}$ for comparison. We have also included the partial decay widths of the three neutrinos since they would be used in the solution to the next exercise.

One finds that calculated values of partial decay width for the lepton pairs are in close agreement with the literature value, deviating by about 0.1% to 1%. The slight deviation could be caused because the $\gamma \rightarrow f\bar{f}$ term [3] and interference terms have been neglected. In case of the quarks, the deviations from the reference values are higher ($\sim 2.7\%$ to 4.6%). This may be due to the fact that additionally, the effect of strong interactions have not been accounted for in our calculations [4].

0.2 Calculation of hadronic, leptonic and total decay widths and cross section

Hadronic decay width: The decay widths for the hadronic mode is given by the sum of the partial decay widths of the u,d,c,s and b quarks:

$$\Gamma_{had} = \Gamma_u + \Gamma_c + \Gamma_d + \Gamma_s + \Gamma_b = 2 \cdot \Gamma_{u,c} + 3 \cdot \Gamma_{d,s,b} = 1674.20 \text{ MeV}$$

‘Charged’ decay width: The charged leptons, e, μ , τ will contribute to this decay width:

$$\Gamma_{charged \text{ leptonic}} = \Gamma_e + \Gamma_\mu + \Gamma_\tau = 3 \cdot \Gamma_{e,\mu,\tau} = 250.17 \text{ MeV}$$

‘Neutral’ (invisible) decay width: The uncharged leptons (ν_e , ν_μ , ν_τ) will contribute to this:

$$\Gamma_{neutral \text{ leptonic}} = \Gamma_{\nu_e} + \Gamma_{\nu_\mu} + \Gamma_{\nu_\tau} = 3 \cdot \Gamma_{\nu_e} = 497.55 \text{ MeV}$$

Total Z^0 decay width: The total decay width for Z^0 will just be the sum of the hadronic, charged leptonic and neutral leptonic decay widths:

$$\Gamma_{total} = \Gamma_{hadronic} + \Gamma_{charged \text{ leptonic}} + \Gamma_{neutral \text{ leptonic}} = 2421.92 \text{ MeV}$$

Partial cross sections at maximum of resonance: At resonance, the formula for calculating partial cross section for $Z^0 \rightarrow f\bar{f}$ becomes:

$$\sigma_f^{peak} = \frac{12\pi\Gamma_e\Gamma_f}{M_Z^2\Gamma_Z^2} \quad (2)$$

The calculated partial cross sections for the different decay channels along with the respective decay widths are tabulated in Table 2.

Decay channel	Decay width / MeV	Partial cross section / $10^{-11} \text{ MeV}^{-2}$
Hadronic (u,d,c,s,b)	1674.20	10.79
Charged leptonic (e, μ , τ)	250.17	1.61
Neutral leptonic (ν_e , ν_μ , ν_τ)	497.55	3.21
Total	2421.92	15.61

Table 2: Calculated decay widths and partial cross sections for different Z^0 decay channels

0.3 Effect of additional generation on width of Z^0 resonance curve

In case it is possible for the Z^0 to decay into an extra generation of light fermions (u,d,e, ν), the total decay width will increase, and the new total decay width will be:

$$\Gamma_{total}^{(new)} = \Gamma_{total} + \Gamma_e + \Gamma_\nu + \Gamma_u + \Gamma_d = 3324.34 \text{ MeV}$$

The percentage increase in the width of the Z^0 resonance curve will be:

$$\frac{\Gamma_{total}^{(new)} - \Gamma_{total}}{\Gamma_{total}} = \frac{902.42}{2421.92} \times 100\% = 37.26\%$$

0.4 Angular distributions of differential cross sections

On studying the dependence of differential cross sections of e^+e^- processes on the azimuthal angle θ , it is found that the s-channel has a symmetrical dependence on θ (with an additional small asymmetric term, in the case of Z^0 mediated process; which will be calculated later):

$$\left(\frac{d\sigma}{d\Omega}\right)_s \propto (1 + \cos^2 \theta) \quad (3)$$

For the case of a t-channel process, it is found that the differential cross section diverges quickly at small θ values [1]:

$$\left(\frac{d\sigma}{d\Omega}\right)_t \propto (1 - \cos \theta)^{-2} \quad (4)$$

While the process $e^+e^- \rightarrow \mu^-\mu^+$ can only take place through the s-channel; the $e^+e^- \rightarrow e^+e^-$ process can occur through both s and t channels. The angular distributions of these two processes are shown in Figure 1. For the $e^+e^- \rightarrow e^+e^-$ process, the contributions from the s and t channels are shown separately as well as their combined contribution to the differential cross section.

Figure 1: Angular distributions of $e^+e^- \rightarrow \mu^+\mu^-$ (left) and $e^+e^- \rightarrow e^+e^-$ (right)

0.5 Calculation of forward-backward asymmetry

We are required to calculate the forward-backward asymmetry factor, A_{FB} in the process $e^+e^- \rightarrow \mu^+\mu^-$. In order to do this, the following formula is used:

$$A_{FB} = \frac{3F_2}{4F_1} \quad (5)$$

where the parameters are given by:

$$F_1(s) = Q_f^2 - 2v_e v_f Q_f \mathcal{R}(\chi) + (v_e^2 + a_e^2)(v_f^2 + a_f^2)|\chi|^2$$

$\sin^2 \theta_W \backslash \sqrt{s} / \text{GeV}$	89.225	91.225	93.225
0.21	-0.0937	0.0762	0.2317
0.23	-0.1639	0.0228	0.1965
0.25	-0.1948	0.0042	0.1906
